

NATIONAL RESEARCH UNIVERSITY

## Credit Risk Evaluation in the Residential Mortgage Market

## Agatha Poroshina

#### Evgeniy Ozhegov

Department of Applied Mathematics and Modeling in Social Systems, Group for Applied Markets and Enterprises Studies

Perm Winter School, January 30th 2014

## Outline

- 1. Motivation
- 2. Stylized Facts
- 3. Literature Review
- 4. Research Questions
- 5. Methodology
- 6. Data Description
- 7. Empirical Results
- 8. Conclusions

This study was carried out with support from "The National Research University Higher School of Economics' Academic Fund Program in 2013-2014, Research Grant No. 12-01-0130 "

## **Motivation of Research**

#### **Internal Risk-Based Approach**

Russian mortgage crisis 2008-2009 The importance of understanding drivers to mortgage defaults The shortcomings of credit risk techniques PD, LGD, EAD, M The experience of developing IRB-systems in Russian bank practice is limited

## **Stylized Facts**

- 1. Probability of default (PD).
- 2. Default 90 days delinquent.
- 3. The absence of the concept of 'mortgage default' in Russian legislation.
- 4. Default drivers:
  - sociodemographic information
  - terms of mortgage contract
  - macroeconomic conditions

# **Literature Review**

Bhutta, Dokko, Shan, 2010, Federal Reserve Board

- Classical binary choice models (single-equation models)

Follain (1990, AREUEA Journal); Rachils, Yezer (1993, Journal of Housing Research)

- Mortgage lending process consists of related or sequentially dependent mortgage lending decisions (multiple-equation models)
- Theoretical model of mortgage lending process consists of multipleequation system

Phillips et al.(1994,1996, Journal of Real Estate Finance and Economics), Ross (2000, Journal of Real Estate Economics), Bajari et. al.(008, National Bureau of Economic Research) etc.

 Isolated modeling processes of the credit underwriting and default leads to biased parameter estimates (sample selection bias)

# **Literature Review**

LaCour-Little, Maxam (2001, Journal of Real Estate Finance and Economics), LaCour-Little et al. (2002, Journal of Real Estate Research)

 Higher predictive power of nonparametric models (kernel regression) for prepayment and default comparing with parametric ones

Stolbov (2012, Journal of NEA), Sternik (2009, Journal of NEA)

- Discussion of triggers of Russian mortgage crisis 2008-2009

Strategy of mortgage residential lending development to 2030, Polterovich, Starkov (2007, Economics and Mathematical methods):

- Discussion of the strategy to develop Russian mortgage market
- Discussion of the strategy of large-scale mortgage based on the transplantation of modified branch of the savings bank and provided model results for Russian market.

## **Research Questions**

- What are determinants of mortgage default within an empirical application to the Russian residential mortgage market?
- 2. Is there difference in results of strictly parameterized and semiparametric models?
- 3. What is the impact of sample selection bias on the default estimates?

# Methodology

# Methodology

### 1) Parametric Approach

- Single-equation model (Probit model)
- Multiple-equation model (Bivariate Probit Model with sample selection correction)

### 2) Semiparametric Approach

Multiple-equation model (Local Polynomial Regression with sample selection correction)

Attanasio et al., 2008, International Economic Review, Das, et al., 2003, The Review of Economic Studies

# Methodology: Parametric Approach

## **Bivariate Probit Model with Sample Selection Correction**

The bivariate probit model with sample selection correction

The classical bivariate probit model
$$y_{1} = x_{1}\beta_{1} + \varepsilon_{1}$$

$$y_{2} = x_{2}\beta_{2} + \varepsilon_{2}$$

$$y_{1} = \begin{cases} 1, if \quad y_{1}^{*} > 0, \\ 0, if \quad y_{1}^{*} \le 0. \end{cases}$$

$$y_{1} = \begin{cases} 1, if \quad y_{1}^{*} > 0, \\ 0, if \quad y_{1}^{*} \le 0. \end{cases}$$

$$y_{2} = \begin{cases} 1, if \quad y_{2}^{*} > 0, \\ 0, if \quad y_{2}^{*} \le 0. \end{cases}$$

$$y_{2} = \begin{cases} 1, if \quad y_{2}^{*} > 0, \\ 0, if \quad y_{2}^{*} \le 0. \end{cases}$$

$$y_{1}^{*} \text{ is observed only if } y_{2}^{*} = 1$$

$$y_{2}^{*} \text{ is observed for all classes}$$

0

#### Heckman's two-stage procedure

$$\hat{\lambda}_i(x_2\hat{\beta}_2) = \frac{\varphi(x_2\hat{\beta}_2)}{\Phi(x_2\hat{\beta}_2)}$$

 $E(y_1 \mid y_1 \text{ is observed}) = x_1 \hat{\beta}_1 + \hat{\rho} \hat{\sigma} \hat{\lambda}_i (x_2 \hat{\beta}_2)$ 

 $(c) \left[ (0) \left( \sigma^2 - c \right) \right]$ 

# Methodology: Semiparametric Approach

$$y_{1}^{*} = x_{1}\beta_{1} + g_{1}(x_{1}) + \varepsilon_{1}$$

$$y_{2}^{*} = x_{2}\beta_{2} + g_{2}(x_{2}) + \varepsilon_{2}$$

$$y_{1} = \begin{cases} 1, if \quad y_{1}^{*} > 0, \\ 0, if \quad y_{1}^{*} \le 0. \end{cases}$$

$$y_{2} = \begin{cases} 1, if \quad y_{2}^{*} > 0, \\ 0, if \quad y_{2}^{*} \le 0. \end{cases}$$

$$y_{1}^{*} \text{ is observed only if } y_{2}^{*} = 1$$

$$y_{2}^{*} \text{ is observed for all classes} \end{cases}$$

$$E(y_1 | x_1, y_2^* > 0) = x_1 \beta_1 + g_1(x_1) + \lambda_i(\varepsilon_1, \varepsilon_2, \hat{y}_2)$$

1, 2, 3 polynomials

#### Least squares estimation

## Data

- 1. Aggregated regional monthly data on the AHML branch performance, mortgage market characteristics and regional macroeconomic variables for the period from 01/08/2008 to 31/08/2012.
- 2. Loan-level data from regional AHML branch (4298 applicants): borrower characteristics, terms of the mortgage contract, property characteristics, and the mortgage performance are available.
  - Reject rate=14%
  - Acceptance rate=86%
    - Issued loans 76%
      - Default rate =6% (90 days delinquency)
      - Non defaulted=94%
    - Unissued loans 24%

| DTI                                       | 2 550 (68.96%) |
| <0.2                                      | 41 (1.11%)     |
| 0.2-0.4                                   | 505 (13.66%)   |
| 0.4-0.6                                   | 379 (10.25%)   |
| 0.6-0.8                                   | 160 (4.33 %)   |
| >=0.8                                     | 63 (1.70%)     |

## **Empirical Results**

Predictive power of mortgage default parametric and semiparametric models are almost the same

right predictions 94.5% and 94.4%

**AUC** are not statistically different for probit, logit, BVP models, but fitted probability of endorsement is statistically significant in BVP with sample selection correction models

 There is sample selection bias. The credit underwriting and mortgage default processes should be modeled jointly.

**PD** is higher for male, borrowers with non declared family status or single, state employees.

## **Empirical Results**

**PD** is higher with higher rate, for loans with maturity less than 15 years, higher loan age.

Not declared income of main borrower is statistically significant in PD. However PD of such borrowers are less then borrowers with small income (< 10 000).

PD increases when average price for 1 square meters in region increases.

- 1. Parametric and semiparametric estimations of credit risk have almost the same predictive power.
- The joint modeling the credit underwriting and mortgage default processes allows to correct for sample selection bias.
- 3. Obtained results can be used to develop the effective risk management systems in credit organizations.

# Thank you for your attention!
